Abstract

We consider the emission of two closed string tachyons from a decaying Dp-brane in bosonic string theory. We study the high energy limit of the emission amplitude by using an analogue to electrostatics. The case where the emitted strings have equal energies is analyzed in detail, and we obtain a relatively simple result for the emission amplitude. We identify expected poles for s- and t-channel emission. In the high energy limit, the amplitude decays exponentially ($\sim e^{-2\pi\omega}$) or faster in the energies ω of the closed strings.

1 Introduction

D-branes in bosonic string theory are unstable, and their decay provides a relatively clean non-trivial example of a time-dependent background in string theory. In supersymmetric string theory, there are also unstable D-branes. The stable D-branes carry charges, so a pair of oppositely charged branes at subcritical separation also becomes unstable and will decay in a similar manner. Investigations of properties of stable D-branes have lead to many important insights, so one may hope that the same will be true for unstable D-branes. The annihilation of an unstable pair of D-branes is a basic process to be understood, and also a building block for many string-based cosmological scenarios. However, D-brane decay is computationally a more demanding process to study. Many simple questions remain unsolved, and have received little attention recently.¹ In this paper we investigate the amplitude for the emission of a pair of closed strings from a decaying brane, in the simple “half S-brane” rolling tachyon decay background [4, 5]. We focus on Dp -branes with $p < 25$.

The single closed string emission channel is relatively well understood, both in bosonic [6–8] and superstring [9] theory, also in the presence of background electric fields, fluxes, or winding [10–13]. Bulk-boundary amplitudes (emission of a closed string from a perturbed D-brane) can also be calculated analytically in bosonic and supersymmetric theories [14–16] (see also [17, 18]).

For multi-string amplitudes, one strategy to calculate the associated n -point (bulk or boundary) amplitudes was based on previous success in bulk Liouville theory [19]. Also in boundary Liouville theory, two-point and three-point functions have well-defined analytical expressions [20–22]. In [23, 24] it was proposed that analytic continuation in coupling $b \rightarrow i$ and field space $\phi \rightarrow iX^0$ to timelike Liouville theory could be used to obtain results in the rolling tachyon background. For bulk-boundary amplitudes, analytic continuation from spacelike theory lead to a result [15, 17] which is in agreement to that of [14] which was based on a more straightforward approach.

Closed string pair production, or associated two-point functions were investigated in [23, 24] but the obtained amplitudes did not display the expected pole structure. Ref. [14] analyzed the problem and identified some potential problems in the analytic continuation. For additional related work, see [25]. We will comment on the analytic properties in more detail in Section 2. For the “full S-brane” background, an interesting prescription to compute disk n -point amplitudes was proposed in [26], and its higher order extensions were investigated in [27]. It would be interesting to investigate this method further to compare the results with those obtained on the half S-brane background. Additional work on string scattering from decaying branes can also be found in [28]. See also the reviews on open string tachyon dynamics [29]

¹Except for the more ambitious open string field theory program, where notable progress in tachyon condensation was obtained in [1, 2] and subsequent work, see [3] for recent discussion in relating the results to boundary conformal theory.

Figure 1: Two channels for emission of a pair of closed strings from a decaying brane. Note the $t \leftrightarrow s$ difference compared to string scattering, see Fig. 2 of [37].

and on Liouville field theory [30].

In this paper we continue developing the approach initiated in [14], in particular we use the relation of correlation functions in the rolling tachyon background to thermal expectation values in a classical log gas of unit charges in two dimensions. The thermal interpretation was further explored in [31–36]. We also use the powerful contour integral representation which was developed in [25] to study n -point boundary functions. Our main result is an amplitude (obtained by working in the high-energy limit) for the emission of a pair of closed string tachyons from the decaying brane. The formula differs from the previously obtained ones by its more promising pole structure. It contains the two expected channels: an s -channel, where an on-shell closed string propagates first before splitting to the two emitted closed strings, and a t -channel, where a pair of on-shell open strings propagate first before closing off to the pair of closed strings, depicted in Figure 1.

Our new calculational ingredient is the use of electrostatics to estimate the leading contribution to the correlation function. While electrostatic analogues have a long history in string theory [38], our approach is reminiscent of that by Gross and Mende [39] (see also [40, 41]), who used electrostatic equilibrium conditions to identify the dominant saddle point contributions to string scattering amplitudes at arbitrary order to determine their high energy behavior. We will also be interested in the high energy limit (for the emitted strings), but we consider only the leading disk amplitude, which is already complicated due to the rolling tachyon background which will correspond to

a thermal charged gas background. In the high energy limit, our amplitude displays the expected exponential $\sim e^{-2\pi\omega}$ suppression, with the sum of the energies of the emitted strings in the exponent.

The paper is organized as follows. Section 2 contains a brief derivation of the perturbative series expansion of the bulk two-point amplitude. We then comment briefly on previous work and analytic properties of the series expansion, and convert it to an integral representation appealing to [25]. Section 3 presents the electrostatics approach and applies it to the emission amplitude calculation. Section 4 introduces Mandelstam variables and presents the result for the amplitude formula and identifies the poles. We then consider its high energy asymptotics in different kinematic limits and find that the amplitude becomes at least exponentially suppressed, as expected. In the end there are three appendices, Appendix A collects some details on kinematics and the amplitude calculation, for readers' convenience. Appendix B discusses an alternative attempt to obtain an exact result for the two-point amplitude, using a Schur polynomial method. Appendix C contains some details of the electrostatics calculations. We also plan to present a more general discussion of the electrostatic approximation in a forthcoming work [42].

2 The bulk two-point amplitude

We begin with setting up the notations for different correlation functions. We work in units where $\alpha' = 1$. The correlation functions are worldsheet path integrals

$$A_2(\{\omega_a, \vec{k}_a\}_{a=1}^2) = \int \prod_{a=1}^2 \frac{d^2 w_a}{2\pi} \left\langle \prod_{a=1}^2 V(w_a, \bar{w}_a) e^{-\delta S_{\text{bdry}}} \right\rangle_{\text{free}}, \quad (1)$$

where the boundary deformation representing the half S-brane [4, 5] is

$$\delta S_{\text{bdry}} = \lambda \int dt e^{X^0(t)}. \quad (2)$$

The vertex operators for the closed string tachyons are

$$V(w_a, \bar{w}_a) = e^{ik_a \cdot X(w_a, \bar{w}_a)}, \quad (3)$$

where $a = 1, 2$. We adopt a notation $\xi_a = -i\omega_a$ and break up the spatial momentum to parallel and perpendicular directions to the unstable Dp-brane: $\vec{k}_a = (\vec{k}_a^{\parallel}, \vec{k}_a^{\perp})$. We also denote $k_a^{\parallel} = (\omega_a, \vec{k}_a^{\parallel}) = (i\xi_a, \vec{k}_a^{\parallel})$. On-shell conditions for the bosonic closed string tachyons are $k_a^2 = \xi_a^2 + (\vec{k}_a^{\perp})^2 = 4$. Furthermore, one finds that the overall (spatial) parallel momentum is conserved: $\vec{k}_1^{\parallel} + \vec{k}_2^{\parallel} = 0$.

The worldsheet correlation functions can be evaluated by first isolating the zero modes from the oscillators, $X^\mu = x^\mu + X'^\mu$, and then expanding the boundary defor-

mation into a power series. This yields

$$A_2(\{\omega_a, \vec{k}_a\}) = \int dx^0 d^p \vec{x}_{\parallel} e^{i \sum_a k_a^\mu x_\mu} \sum_{N=0}^{\infty} \frac{(-z)^N}{N!} \int \prod_{a=1}^2 \frac{d^2 w_a}{2\pi} \times \prod_{i=1}^N \frac{dt_i}{2\pi} \left\langle \prod_{i=1}^N e^{X^{i0}(t_i)} \prod_{a=1}^2 e^{i k_a \cdot X'(w_a, \bar{w}_a)} \right\rangle, \quad (4)$$

where we introduced $z = 2\pi\lambda e^{x^0}$.

After working out the contractions, with the Neumann and Dirichlet Green's functions (see Appendix A and, *e.g.*, [14] for more details), (4) becomes

$$A_2(\{\omega_a, \vec{k}_a\}) = \int dx^0 d^p \vec{x}_{\parallel} e^{i \sum_a k_a^\mu x_\mu} \bar{A}_2(x^0) \quad (5)$$

$$\begin{aligned} \bar{A}_2(x^0) &= \sum_{N=0}^{\infty} (-z)^N \int \prod_{a=1}^2 \frac{d^2 w_a}{2\pi} |w_1 - w_2|^{k_1 \cdot k_2} \\ &\times \prod_{a,b=1}^2 |1 - w_a \bar{w}_b|^{\frac{1}{2}(k_a^\parallel \cdot k_b^\parallel - \vec{k}_a^\perp \cdot \vec{k}_b^\perp)} Z_2(\{w_a, k_a\}; N), \end{aligned} \quad (6)$$

where

$$Z_2(\{w_a, k_a\}; N) = \frac{1}{N!} \int \prod_{i=1}^N \frac{dt_i}{2\pi} \prod_{1 \leq i < j \leq N} |e^{it_i} - e^{it_j}|^2 \prod_{a=1}^2 |1 - w_a e^{-it_i}|^{2\xi_a}. \quad (7)$$

2.1 Some general comments

We fix the residual global conformal symmetry on the disk by placing the other bulk vertex operator to the origin ($w_2 = 0$) and the other one to the real axis at $1 > w_1 = r > 0$. Let the (imaginary) energy of the closed string vertex at $w_1 = r$ be $\xi_1 \equiv \xi$ and the energy of the string at $w_2 = 0$ be ξ_2 . The first challenge in calculating the amplitude is the integrals (7), which now become

$$Z_2(r, \xi; N) = \frac{1}{N!} \int \left[\prod_{i=1}^N \frac{dt_i}{2\pi} |r - e^{it_i}|^{2\xi} \right] \left[\prod_{1 \leq i < j \leq N} |e^{it_i} - e^{it_j}|^2 \right]. \quad (8)$$

We can make the following general remarks:

- For $0 \leq r < 1$ the integral $Z_2(r, \xi; N)$ is an analytic function of ξ .
- For negative integer ξ and for $N \geq |\xi|$ the integral can be evaluated by using identities of the Schur polynomials [24] giving $Z_2(r, \xi; N) = (1 - r^2)^{-\xi^2}$. For positive integer ξ the integral is a polynomial in r , and may be written down explicitly by using Schur polynomials (see Appendix B).

- In the limit $N \rightarrow \infty$ authors of [14] also find $Z_2(r, \xi; N) \rightarrow (1 - r^2)^{-\xi^2}$.
- For $r \rightarrow 1$, and if $\text{Re } \xi > -1/2$,² $Z_2(r, \xi; N)$ approaches smoothly the boundary-one-point and bulk-boundary functions [14] (see also [15]).

In the final amplitude the interesting region is $\xi = -i\omega$, where ω is the energy of the closed string at $w_1 = r$. In the case of (integrated) boundary amplitudes, it is possible to analytically continue from positive $\text{Re } \xi$ to imaginary values [25]. The bulk integrals approach smoothly the boundary ones for positive $\text{Re } \xi$ in the limit $r \rightarrow 1$, so it is natural to assume that the $\text{Re } \xi > 0$ region may be a good starting point to study the complete bulk amplitudes.

There are closely related problems where the scattering amplitude, the sum of N over an infinite series of terms, is essentially equal to a generic N th term after analytically continuing $N \rightarrow -i \sum_a \omega_a$. In spacelike Liouville theory, for bulk amplitudes a related observation was made in [43]. In [14] it was observed for the bulk-boundary amplitude in the decaying D-brane background. Then, ref. [25] constructed a detailed contour integration method to show how boundary amplitudes reduce to the analytical continuation of a term. Following [14, 25] we expect that the bulk amplitude is given by a certain analytic continuation to negative N :

$$A_2 = \frac{\pi(2\pi\lambda)^{-\xi-\xi_2}}{\sin \pi(\xi + \xi_2)} \int_0^1 dr r r^{k_1 \cdot k_2} (1 - r^2)^{\frac{1}{2}((k_1^\parallel)^2 - (\vec{k}_1^\perp)^2)} Z_2(r, \xi; N = -\xi - \xi_2) . \quad (9)$$

In the integrand of (9), at this point we only know the term Z_2 through its definition in (8), which is quite complicated. However, it allows us to make some observations about the pole structure of the amplitude. There singularities at each endpoint $r = 0, 1$ in the r integral give rise to pole structures, as in scattering from a stable D-brane [44], see [37] for a review.³ From (8) we can see that Z_2 is real analytic at $r = 0$ and even in r . It is also analytic at $r = 1$ for $\text{Re } \xi > -1/2$. Consequently, the singularities at the endpoints originate from the factor $r r^{k_1 \cdot k_2} (1 - r^2)^{\frac{1}{2}((k_1^\parallel)^2 - (\vec{k}_1^\perp)^2)}$, which is the same as in scattering from the stable D-brane. Let us consider the poles from $r = 0$ in more detail. We may expand Z_2 as a Taylor series at $r = 0$,

$$\begin{aligned} Z_2(r, \xi; N = -\xi - \xi_2) &= Z_2(0, \xi; N = -\xi - \xi_2) + \frac{1}{2} r^2 \frac{\partial^2}{\partial r^2} Z_2(r, \xi; N = -\xi - \xi_2)|_{r=0} + \cdots \\ &= 1 + a_2(\xi, \xi_2) r^2 + \cdots , \end{aligned} \quad (10)$$

²Authors of [14] use functional relations which hold only for $\text{Re } \xi > -1/2$ in their discussion of the $r \rightarrow 1$ limit.

³On the other hand, scattering from a stable D-brane corresponds to the $N = 0$ term in the series expansion (4).

where $a_2(\xi, \xi_2)$ is the proper analytic continuation of the series coefficient⁴ to $N = -\xi - \xi_2$. Integrating over r term by term in (9) then yields

$$\begin{aligned} A_2 &= \frac{\pi(2\pi\lambda)^{-\xi-\xi_2}}{\sin \pi(\xi + \xi_2)} \int_0^1 dr r r^{k_1 \cdot k_2} \left[1 + \left(a_2(\xi, \xi_2) - \frac{1}{2}(k_1^{\parallel})^2 + \frac{1}{2}(\vec{k}_1^{\perp})^2 \right) r^2 + \dots \right] \\ &= \frac{\pi(2\pi\lambda)^{-\xi-\xi_2}}{\sin \pi(\xi + \xi_2)} \left[\frac{1}{k_1 \cdot k_2 + 2} + \frac{a_2(\xi, \xi_2) - \frac{1}{2}(k_1^{\parallel})^2 + \frac{1}{2}(\vec{k}_1^{\perp})^2}{k_1 \cdot k_2 + 4} + \dots \right]. \end{aligned} \quad (11)$$

The poles are located at $k_1 \cdot k_2 = -2, -4, \dots$, as in scattering from ordinary D-branes [37, 44]. The above calculation highlights the structure of the integrand at $r = 0$.

Similarly one can check that the singularity at $r = 1$ gives rise to poles at $2(k_1^{\parallel})^2 = 2, 0, -2, \dots$ where we used the mass-shell condition $k_1^2 = 4$.

The remaining paper focuses on developing an electrostatic approximation for Z_2 . It is analytic at $r = 0, 1$, so the poles indeed arise as described above, and we can verify the expressions explicitly. We shall discuss in detail only the case $\xi = \xi_2$ where the production amplitude is symmetric.⁵

3 Electrostatic calculation

Our starting point is to view [14, 16, 25, 31] Z_2 as the partition function of a Coulomb gas [45], with two additional external charges ξ, ξ_2 at fixed positions. We write it in the form

$$Z_2(\{\xi_a\}; N) = \frac{1}{N!} \int \prod_{i=1}^N \frac{dt_i}{2\pi} e^{-2H}, \quad (12)$$

where the Hamiltonian H reads

$$H = - \sum_{1 \leq i < j \leq N} \log |e^{it_i} - e^{it_j}| - \sum_{i=1}^N \sum_{a=1}^2 \xi_a \log |e^{it_i} - w_a|, \quad (13)$$

and we fixed the inverse temperature to $\beta = 2$. As seen from the Hamiltonian, we have an ensemble of N unit charges on the circle at $e^{it_1}, \dots, e^{it_N}$, which interact via

⁴See Appendix B for a calculation of the series coefficients for $N = 0, 1, 2, \dots$. In particular, for integer N one can extract from eqn. (71) that $a_2 = \xi^2 \delta_{N>0}$.

⁵The reason for this restriction is a puzzling observation for which we do not have a good explanation at the moment. When we use conformal symmetry to place the other vertex operator to origin and the other one to $w = r$, the amplitude (5)-(7) becomes asymmetric with respect to the exchange $1 \leftrightarrow 2$ of the strings, if they have different energies, $\xi \neq \xi_2$. As a result, the poles seem not to respect the exchange symmetry. So, the use of conformal symmetry to fix the vertex positions in the rolling tachyon background involves a subtlety, unless $\xi = \xi_2$, in which case the strings are exchange symmetric “in the time direction”.

the Coulomb potential.⁶ They are subject to an external electric field created by two fixed charges.

A useful strategy is to study the system using classical electrostatics, first in the limit of large number N of unit charges. In this limit the unit charges can be treated as a continuous charge distribution. Its density is modified by the external charges ξ_a and we are interested in finding the electrostatic equilibrium configuration. Notice that the present system is analogous to the circular unitary ensemble [5] of random matrix theory, where the connection to the Coulomb gas is a standard tool. Our method indeed resembles the electrostatic derivation of Wigner's semi-circle law [46] (see also [47]). It is also reminiscent of the work of Gross and Mende [39], who used electrostatic equilibrium conditions to identify the dominant saddle point contributions to string scattering amplitudes at arbitrary order to determine their high energy behavior. We will also consider the high energy limit (for the emitted strings), but we restrict to the leading disk amplitude, which is already complicated due to the charge density background. A more detailed description of our method and other applications will be discussed elsewhere [42], here we focus on aspects that are relevant for the bulk two-point amplitude.

We use a saddle point approach and write

$$\log Z_2(\{\xi_a\}; N) \simeq -2H_0 \simeq -2\mathcal{E}_{\text{tot}} , \quad (14)$$

where H_0 is the minimum value of the Hamiltonian (13) and $\mathcal{E}_{\text{tot}}$ is the (total) electrostatic energy of the corresponding equilibrium configuration with continuous charge densities. The string production amplitude (9) requires $N = -\xi - \xi_2$, so that we need to study the electrostatic problem in the regime $N \sim \xi \sim \xi_2$. It turns out that nontrivial electrostatic configurations are indeed obtained when the external charges are of the same order as the sum of the unit charges. Slightly more precisely, the electrostatic configurations of interest to us are in the limit $N \rightarrow \infty$ with the ratios N/ξ and N/ξ_2 fixed.⁷

Let us then discuss how the total electrostatic energy $\mathcal{E}_{\text{tot}}$ is calculated. The first ingredient is the (complex) potential $V(w)$, the physical potential is the real part

$$U(w) = \text{Re } V(w) . \quad (15)$$

The potential is sourced by the continuous charge density $\rho(\phi)$ (by which we approximate the N unit charges in the $N \rightarrow \infty$ limit, with the normalization $N = \oint d\phi \rho(\phi)$) and the external charges ξ_a ,

$$V(w) = - \int d\phi \rho(\phi) \log(w - e^{i\phi}) - \sum_a \xi_a \log(w - w_a) + \text{const.} . \quad (16)$$

⁶Other unstable D-brane backgrounds correspond to different Coulomb gases [32–34].

⁷Recall that the behavior of Z_2 in the limit $N \rightarrow \infty$ with ξ_a and w_a fixed can be calculated by using the asymptotics of Toeplitz determinants [14, 48–50].

We choose the zero level of the potential by setting the last constant term to zero. We then need to find $V(w)$ and $\rho(\phi)$ in the equilibrium configuration. We are interested in the configurations where $\rho(\phi)$ is strictly positive within a domain C of the unit circle and vanishes elsewhere.⁸ Then solving the equilibrium configuration reverts to a standard potential problem of classical electrostatics including the external charges ξ_a and a conductor which fills the domain C . In particular, in the equilibrium configuration the physical potential $U(e^{i\phi})$ must take a constant value,

$$U(e^{i\phi}) = U_0 , \quad (17)$$

in C : If the potential would vary within C , the charges on the conductor would be subject to forces and move until the potential adjusts to a constant value.

The electrostatic energy is defined as the energy of the system in the equilibrium configuration, and may be expressed in terms of $\rho_0(\phi)$ as

$$\begin{aligned} \mathcal{E}_{\text{tot}} &= -\frac{1}{2} \int d\phi_1 d\phi_2 \rho_0(\phi_1) \rho_0(\phi_2) \log |e^{i\phi_1} - e^{i\phi_2}| \\ &\quad - \sum_a \xi_a \int d\phi \rho_0(\phi) \log |e^{i\phi} - w_a| \\ &\equiv \mathcal{E}_c + \mathcal{E}_{c-\xi} . \end{aligned} \quad (18)$$

We again set a possible constant contribution to zero. Then the energy matches with the continuum limit of the Hamiltonian (13) and thus approximates the saddle point value of $-\frac{1}{2} \log Z_2$. By using the fact that the physical potential $U(e^{i\phi})$ is constant within the domain C of nonzero ρ_0 , we can express the result as

$$\mathcal{E}_{\text{tot}} = \frac{N}{2} U_0 + \frac{1}{2} \mathcal{E}_{c-\xi} , \quad (19)$$

where the first term includes one half of the “interaction energy” $\mathcal{E}_{c-\xi}$. Hence, to calculate $\mathcal{E}_{\text{tot}}$ and the leading behavior of Z_2 for large $N \sim \xi \sim \xi_2$, it is sufficient to find U_0 and $\mathcal{E}_{c-\xi}$. We present a general method for this in Appendix C.

In the next two subsections we work out the electrostatics approximation of the (two-point) bulk amplitude explicitly. We can omit the charge ξ_2 at the origin since it does not affect the calculation. The treatment of the other (real) charge ξ at the real line with $0 < w_1 = r < 1$ is divided to two regimes, depending on the values of r and ξ/N . For small values of r the charge ξ affects the charge distribution on the unit circle less, and it remains strictly positive for all $\phi = \arg w$. For $r \rightarrow 1$ (assuming $\xi > 0$) the charge ξ creates a gap in the charge distribution on the circle in the interval $-\phi_c < \phi < \phi_c$.⁹ We discuss first the small r case.

⁸In this paper it is sufficient to assume that the domain C of non-zero $\rho(\phi)$ is connected, that is, an arc.

⁹The distribution remains strictly positive if ξ is negative and $N > |\xi|$. We shall consider the gap creation only for positive ξ where the $r \rightarrow 1$ limit of Z_2 matches with the one-point boundary function [14].

3.1 Small r

For small r one needs to solve the potential problem on the unit disk (without gaps), which is easily done by using a mirror charge. One can check that $U(e^{i\phi}) = U_0 = 0$ in this case when the constant term in (16) is set to zero. At electrostatic equilibrium, the potential becomes

$$V(w) = -\xi \log \frac{w-r}{1-wr} . \quad (20)$$

The first part of (16), the contribution from the continuous distribution on the circle, becomes $V_c(w) = +\xi \log(1-wr)$ at equilibrium, which in turn equals the potential of the mirror charge at $w = 1/r$. As mentioned above, we dropped the trivial contribution $-\xi_2 \log w$ due to the charge at the origin which neither affects the charge densities nor the total energy. The equilibrium charge distribution on the unit circle is

$$\rho_0(\phi) = \frac{1}{2\pi} (N + \xi) - \frac{1}{2\pi} |V'(w)|_{w=e^{i\phi}} = \frac{1}{2\pi} \left(N + \xi - \xi \frac{1-r^2}{1+r^2-2r\cos\phi} \right) , \quad (21)$$

where the first (constant) term is fixed by $\oint d\phi \rho(\phi) = N$ and the second (ϕ dependent) term is the charge density induced by the charge ξ at $w_1 = r$. The absence of the gap requires that ρ is positive, *i.e.*, that

$$r < \frac{N}{N+2\xi} \equiv r_c , \quad (22)$$

which defines what we mean by “small r ”. The total energy at equilibrium becomes

$$\mathcal{E}_{\text{tot}} = \frac{1}{2} \mathcal{E}_{c-\xi} = \frac{\xi}{2} V_c(w=r) = \frac{\xi^2}{2} \log(1-r^2) . \quad (23)$$

Notice that in the large N limit with fixed ξ we have $r_c \rightarrow 1$, and the result (23) is valid for all r . Hence in this limit we may use the result directly in (14),

$$Z_2(\xi; N) \propto e^{-2\mathcal{E}_{\text{tot}}} = (1-r^2)^{-\xi^2} ; \quad N \rightarrow \infty , \quad (24)$$

which indeed reproduces exactly the large N result of eqn. (5.13) in [14]. However, as we will see next, at large r we obtain in general a different result.

3.2 Large r

As we saw in (22), for $r > N/(N+2\xi)$ there is a gap on the unit circle charge distribution. The electrostatic problem becomes more difficult. We present a general method to find the equilibrium charge density in the presence of gaps in Appendix C. Here we focus on the results in the case of one gap $\hat{n} = 1$ and one external charge $n = 1$ which is relevant at large r .

Appendix C performs the calculation in a simplified geometry, where the unit disk (in w coordinates) is mapped onto the upper half plane (z coordinates) by

$$z = q(w) = i\beta \frac{1-w}{1+w} = i \cot(\phi_c/2) \frac{1-w}{1+w}, \quad (25)$$

where ϕ_c will parameterize the location of the gap in the charge density. In the electrostatic problem (on the w plane), there is an induced image charge $-N - \xi$ at infinity, so that the net charge is zero. Following the point at infinity in the mapping q in (25), the image appears as an additional charge at $z = q(\infty)$ on the z plane. In the notation of Appendix C the actual charge is $\xi_n = \xi_1 \equiv \xi$ and the image charge is $\xi_{n+1} = \xi_2$:

$$\begin{aligned} \xi_1 &= \xi & \text{at} & \quad z = i\delta(r)\beta \quad (w = r) \\ \xi_2 &= -N - \xi & \text{at} & \quad z = -i\beta \quad (w = \infty), \end{aligned} \quad (26)$$

where $\beta = \cot(\phi_c/2)$ and

$$\delta(r) = \frac{1-r}{1+r}. \quad (27)$$

The asymptotic behavior of the electric field leads to a constraint (eqn. (84) in Appendix C) which gives a relation

$$\left(1 + \frac{N}{\xi}\right)^2 = \frac{1 + \delta^2(r)\beta^2}{1 + \beta^2} \quad (28)$$

or equivalently

$$\cos^2 \frac{\phi_c}{2} = \frac{1 - \chi^2}{1 - \delta(r)^2} = \frac{1 - \left(\frac{\xi}{N+\xi}\right)^2}{1 - \left(\frac{1-r}{1+r}\right)^2}, \quad (29)$$

where $\chi = \xi/(N + \xi)$. Notice that ϕ_c vanishes at $r = r_c = N/(N + 2\xi)$ which signals the disappearance of the gap. By using eqs. (88) and (90) we find for the constant value of the potential

$$U_0 = -\frac{N}{2} \log \frac{1-\chi}{1-\delta(r)} - \frac{N+2\xi}{2} \log \frac{1+\chi}{1+\delta(r)}, \quad (30)$$

while the interaction energy of (91) is given by

$$\mathcal{E}_{c-\xi} = \xi(N + \xi) \left[\log \frac{1+\delta(r)}{1+\chi} + \chi \log \frac{4\chi}{(1+\chi)(1+\delta(r))} \right]. \quad (31)$$

The total energy thus reads

$$\begin{aligned} \mathcal{E}_{\text{tot}} &= \frac{N}{2} U + \frac{1}{2} \mathcal{E}_{c-\xi} \\ &= -\frac{(N+2\xi)^2}{4} \log \frac{1+\chi}{1+\delta(r)} - \frac{N^2}{4} \log \frac{1-\chi}{1-\delta(r)} + \frac{\xi^2}{2} \log \frac{4\chi}{(1+\delta(r))^2}. \end{aligned} \quad (32)$$

4 High energy behavior

Let us then apply the electrostatic results to estimate the string production amplitude of (9). In the bulk case there is a subtlety with analytic continuation of [14, 25] $N \rightarrow -\xi - \xi_2$. When r is kept fixed, the integral can be approximated by the “large r ” result (32) for $N \lesssim N_c$, where $N_c = 2\xi r/(1-r)$, whereas “small r ” approximation (23) works for $N \gtrsim N_c$. Thus there is a discontinuity at $N = N_c$, which leads to apparent problems with the analytic continuation. The sum that we should calculate reads

$$\bar{A}_2(z) \sim \sum_{N=0}^{\infty} (-z)^N Z_2(r, \xi; N) \simeq \sum_{N=0}^{\infty} (-z)^N e^{-2\mathcal{E}_{\text{tot}}} , \quad (33)$$

where $z = 2\pi\lambda e^{x^0}$ and $\mathcal{E}_{\text{tot}}$ is given by either (32) if $N \lesssim N_c$ or (23) if $N \gtrsim N_c$. The sum is well convergent and insensitive to the actual value of N_c for $|z| < 1$. For continuation to $|z| > 1$ we would like to apply the contour integral method of [25]. However, the discontinuity at $N = N_c$ seems to be problematic, if r is held fixed. The sum $\bar{A}_2(z)$ is sensitive to N_c and consequently diverges fast for $z \rightarrow \infty$ with an arbitrary proportionality constant, whence it is not possible to integrate the amplitude over x^0 . Working directly at imaginary $\xi = -i\omega$ might improve the convergence, but the analytic continuation is still tricky.

Remarkably, the problems disappear if r is integrated over first. Hence we define the integrated partition function

$$\begin{aligned} \int_0^1 dr k(r) Z_2(r, \xi; N) &\simeq \int_0^{r_c} dr k(r) (1-r^2)^{-\xi^2} + \int_{r_c}^1 dr k(r) \left(\frac{1+\chi}{1+\delta(r)} \right)^{(N+2\xi)^2/2} \\ &\quad \times \left(\frac{1-\chi}{1-\delta(r)} \right)^{N^2/2} \left(\frac{4\chi}{(1+\delta(r))^2} \right)^{-\xi^2} \\ &\equiv \bar{Z}(\xi; N) , \end{aligned} \quad (34)$$

where $r_c = N/(N+2\xi)$ and $k(r)$ can be any arbitrary analytic function, but we will choose it appropriately below in (36). Now $\bar{Z}$ is an analytic function of N , and can be continued analytically to all complex N plane. It has a few branch cuts: branch points are found whenever the endpoint of the integration, r_c , hits singularities of the integrand. Branches are given by the various winding possibilities of the integration path. The singularities are found at $r = 0, \pm 1$, and ∞ , giving for the branch points $N = 0, -\xi, -2\xi$, and ∞ .

It is straightforward to check that $\bar{Z}$ grows only as a power law as $N \rightarrow \infty$ in any direction on the complex plane. Hence, following the analysis of [25], we can apply the contour integration method, which gives our conjecture for the high energy behavior of the bulk two-point function

$$A_2 \simeq \int dx^0 e^{(\xi+\xi_2)x^0} \sum_{N=0}^{\infty} (-z)^N \bar{Z}(N) = \frac{\pi(2\pi\lambda)^{-\xi-\xi_2}}{\sin \pi(\xi+\xi_2)} \bar{Z}(\xi; N = -\xi - \xi_2) , \quad (35)$$

where we fixed (see (9))

$$k(r) = r r^{k_1 \cdot k_2} (1 - r^2)^{\frac{1}{2}((k_1^{\parallel})^2 - (\vec{k}_1^{\perp})^2)} \quad (36)$$

and omitted the trivial factor $\delta(\vec{k}_1^{\parallel} + \vec{k}_2^{\parallel})$. Explicitly,

$$\begin{aligned} A_2 \simeq & \frac{\pi(2\pi\lambda)^{-\xi-\xi_2}}{\sin \pi(\xi + \xi_2)} \left[\int_0^{\hat{r}_c} dr r^{k_1 \cdot k_2 + 1} (1 - r^2)^{\frac{1}{2}(-\xi^2 + (\vec{k}_1^{\parallel})^2 - (\vec{k}_1^{\perp})^2)} \right. \\ & + \int_{\hat{r}_c}^1 dr r^{k_1 \cdot k_2 + 1} (1 - r^2)^{\frac{1}{2}((k_1^{\parallel})^2 - (\vec{k}_1^{\perp})^2)} \\ & \times \left(\frac{(1 + \delta(r))^2}{4\hat{\chi}} \right)^{\xi^2} \left(\frac{1 + \hat{\chi}}{1 + \delta(r)} \right)^{(\xi - \xi_2)^2/2} \left(\frac{1 - \hat{\chi}}{1 - \delta(r)} \right)^{(\xi + \xi_2)^2/2} \left. \right], \end{aligned} \quad (37)$$

where the hats indicate that analytic continuation was imposed:

$$\hat{r}_c = \frac{\xi_2 + \xi}{\xi_2 - \xi}, \quad \hat{\chi} = -\frac{\xi}{\xi_2}, \quad \text{and} \quad \delta(r) = \frac{1 - r}{1 + r}. \quad (38)$$

Here we may use the momentum conservation in (spatial) directions parallel to the Dp -brane and the on-shell conditions, which lead to

$$\begin{aligned} \vec{k}_1^{\parallel} &= -\vec{k}_2^{\parallel} \equiv \vec{k}^{\parallel} \\ (\vec{k}_1^{\perp})^2 + \xi^2 &= (\vec{k}_2^{\perp})^2 + \xi_2^2 = 4 - (\vec{k}^{\parallel})^2. \end{aligned} \quad (39)$$

Notice that the result seems to be asymmetric under the reordering $1 \leftrightarrow 2$ of the vertices unless $\xi = \xi_2$ as suggested by the analysis of the pole positions in Section 2.1. In general $\xi \neq \xi_2$ unless the brane is space-filling ($p = 25$). We will now focus on the symmetric case $\xi = \xi_2$, which leads to a drastic simplification of the result (37). By (39) this then also sets $|\vec{k}_1^{\perp}| = |\vec{k}_2^{\perp}|$. Let us define the kinematic variables

$$\begin{aligned} s &= k_1 \cdot k_2 \\ t &= 2(k_1^{\parallel})^2 = 2(k_2^{\parallel})^2 = 8 - (\vec{k}_1^{\perp})^2 - (\vec{k}_2^{\perp})^2 \\ u &= \frac{(\vec{k}_1^{\perp} - \vec{k}_2^{\perp})^2}{2}, \end{aligned} \quad (40)$$

which are motivated by the standard conventions (see Appendix A) for scattering from a stable D-brane [37, 44] but should not be regarded as true Mandelstam variables.¹⁰ We have crossed $s \leftrightarrow t$ to obtain a setting which corresponds to string production by the brane rather than scattering off the brane.

¹⁰These variables are not directly linked to $2 \rightarrow 2$ scattering which is the case for the stable D-brane (Appendix A). For example, even after fixing $\xi = \xi_2$ there are three independent kinematic variables in the present case. Hence u cannot be expressed in terms of s and t in contrast to usual $2 \rightarrow 2$ scattering.

For equal energies (37) is apparently singular, because N is continued analytically to the value -2ξ where the integral has a branch point. Hence we need to check the details of the analytic continuation carefully. We choose a natural branch where the continuation is done from positive values of N via the path

$$N = 2\xi e^{i\varphi} ; \quad \varphi = 0 \dots \pi . \quad (41)$$

Then, in particular, $\hat{r}_c \rightarrow \infty$ along the positive imaginary axis, or more precisely the path $\text{Re } \hat{r}_c = 1/2$. The amplitude becomes

$$A_2 \simeq \frac{\pi(2\pi\lambda)^{-2\xi}}{2\sin 2\pi\xi} \left\{ e^{i\pi\xi^2} \int_0^1 dx x^{\frac{s}{2}-\xi^2} (1-x)^{\frac{t}{2}-2} - e^{i\frac{\pi s}{2}} \int_0^\infty dy \left[y^{\frac{s}{2}-\xi^2} (1+y)^{\frac{t}{2}-2} - y^{\frac{s}{2}} (1+y)^{\frac{t}{2}-\xi^2-2} \right] \right\} , \quad (42)$$

where we substituted $x = r^2$ and $y = -r^2$. After using identities of the gamma functions, the result simplifies to

$$\begin{aligned} A_2 &\simeq -\frac{i\pi e^{i\frac{\pi s}{2}}(2\pi\lambda)^{2i\omega}}{2\sinh 2\pi\omega} \left[e^{i\frac{\pi u}{2}} B\left(\frac{t}{2}-1, \frac{u}{2}-1\right) + B\left(\frac{s}{2}+1, \frac{u}{2}-1\right) \right] \\ &= -\frac{i\pi e^{i\frac{\pi s}{2}}(2\pi\lambda)^{2i\omega}}{2\sinh 2\pi\omega} \left[e^{i\frac{\pi u}{2}} \frac{\Gamma\left(\frac{t}{2}-1\right)}{\Gamma\left(\frac{t+u}{2}-2\right)} + \frac{\Gamma\left(\frac{s}{2}+1\right)}{\Gamma\left(\frac{s+u}{2}\right)} \right] \Gamma\left(\frac{u}{2}-1\right) , \end{aligned} \quad (43)$$

where $\omega = \omega_1 = \omega_2 = i\xi$.

Notice that (43) has the expected s - and t -channel poles at $s = -2, -4, -6, \dots$ and at $t = 2, 0, -2, \dots$ which arise from the endpoints at $r = 0$ and $r = 1$ of the integral in (37), respectively. It is possible to check that the residues of the first few poles are in accord with the general expectations of Section 2.1. The last gamma function produces an additional pole at $u = 0$, while at $u = 2$ the expression in square brackets vanishes which cancels the next pole. The following poles at negative u are unphysical since $u \geq 0$ by definition. The $u = 0$ singularity corresponds to production of strings which have parallel momenta in the directions perpendicular to the Dp-brane, $\vec{k}_1^\perp = \vec{k}_2^\perp$, $p < 25$. The amplitude is also singular at $\omega = 0$.

4.1 Kinematic limits

To conclude our analysis, let us consider the asymptotic behavior of the $\xi = \xi_2$ amplitude (43) in different kinematic limits. We notice that the kinematic variables can be written as

$$\begin{aligned} s &= 4 - 2(\vec{k}^\parallel)^2 - (\vec{k}^\perp)^2(1 - \cos\theta) \\ t &= 8 - 2(\vec{k}^\perp)^2 \\ u &= (\vec{k}^\perp)^2(1 - \cos\theta) , \end{aligned} \quad (44)$$

Figure 2: This figure illustrates the kinematic variables: the spatial momenta of the emitted strings $\vec{k}_i$ with the angles θ, ψ .

where $(\vec{k}^\perp)^2 \equiv (\vec{k}_1^\perp)^2 = (\vec{k}_2^\perp)^2$ and θ is the angle between $\vec{k}_1^\perp$ and $\vec{k}_2^\perp$ (see figure 2). Before going to the explicit asymptotics, we make an important general observation: the amplitude in (43) vanishes exponentially ($\sim e^{-2\pi\omega}$ or faster) in the high energy limit. Recall that one-point amplitude [6] behaves as $\sim e^{-\pi\omega}$. This result follows since the sums of the arguments of the two beta functions in (43) are bounded from above,

$$\begin{aligned} \frac{t+u}{2} - 2 &= 2 - (\vec{k}^\perp)^2 \frac{1 + \cos \theta}{2} \leq 2 \\ \frac{s+u}{2} &= 2 - (\vec{k}^\parallel)^2 \leq 2, \end{aligned} \quad (45)$$

which excludes the region where the beta functions would grow exponentially for $\omega \rightarrow \infty$. They can have a power-like behavior in ω if at least one of the sums is fixed for $\omega \rightarrow \infty$, in which case the behavior $\sim e^{-2\pi\omega}$ arises from the factor $1/\sinh 2\pi\omega$ that multiplies the beta functions. The same factor is responsible for the suppression of the one-point amplitude. In both cases the exponent contains the total energy of the emitted strings. In particular this suggests that in the brane decay the two-string emission channel will be as important as the one-string channel. However, we would need to study decay into massive string states and the phase space factors before drawing conclusions.

Let us consider the following special limits:

- I $(\vec{k}^\parallel)^2 \rightarrow \infty$ with $(\vec{k}^\perp)^2$ fixed, corresponding to string production parallel to the decaying brane
- II $(\vec{k}^\perp)^2 \rightarrow \infty$ with $(\vec{k}^\parallel)^2$ (and θ) fixed, corresponding to string production perpendicular to the decaying brane

III $(\vec{k}^\perp)^2 \rightarrow \infty$ with $(\vec{k}^\parallel)^2$ and $(\vec{k}^\perp)^2(1 + \cos \theta)$ (or equivalently $\vec{k}_1^\perp + \vec{k}_2^\perp$) fixed, corresponding to string production perpendicular to the decaying brane such that the backreaction to the brane remains finite.

Notice that all these limits are reasonable, since $\omega^2 = \vec{k}^2 - 4 \rightarrow \infty$ in each case validating the electrostatic approximation. Recall that any subleading terms of the electrostatic approximation were not included, and hence results for subleading asymptotics (which we shall anyhow write down) are not reliable. Also notice that there are plenty of poles in the physically meaningful region. We only state the leading overall behavior “averaged over the poles”, so the subleading terms may be significant very near their poles.

The limit I means taking $s \rightarrow -\infty$ with t and u fixed. For $u > 2$ the factor in the square brackets of (43) approaches a constant since the latter, s dependent term decays,

$$A_2 \simeq -\frac{i\pi e^{i\frac{\pi s}{2}}(2\pi\lambda)^{2i\omega}}{2 \sinh 2\pi\omega} e^{i\frac{\pi u}{2}} \frac{\Gamma\left(\frac{t}{2} - 1\right) \Gamma\left(\frac{u}{2} - 1\right)}{\Gamma\left(\frac{t+u}{2} - 2\right)}, \quad (46)$$

while for $0 < u < 2$ the latter term dominates and we find

$$A_2 \simeq \frac{i\pi e^{i\frac{\pi s}{2}}(2\pi\lambda)^{2i\omega}}{2 \sinh 2\pi\omega} \Gamma\left(\frac{u}{2} - 1\right) \frac{\sin[\pi(s+u)/2]}{\sin[\pi s/2]} \left(-\frac{s}{2}\right)^{1-\frac{u}{2}}. \quad (47)$$

Thus for any u the absolute value of the amplitude vanishes exponentially $\sim e^{-2\pi\omega}$, as expected. The amplitude has also a very rapidly varying phase $\sim e^{-i\pi\omega^2}$. The subleading behavior which arises from the terms in the square brackets is likely to be modified by the nonleading terms of the electrostatic limit which we have neglected.

The limit II corresponds to $s, t \rightarrow -\infty$ while $u \rightarrow +\infty$ such that $t+u \rightarrow -\infty$ and $s+u = 4 - 2(\vec{k}^\parallel)^2$ remains fixed. Then the first term in the square brackets vanishes exponentially, and the contribution from the second term leads to

$$A_2 \simeq \frac{i\pi e^{i\frac{\pi s}{2}}(2\pi\lambda)^{2i\omega}}{2 \sinh 2\pi\omega} \frac{\pi}{\Gamma\left(\frac{s+u}{2}\right) \sin \frac{\pi s}{2}} \left(-\frac{s}{2}\right)^{\frac{s+u}{2}-1}. \quad (48)$$

Hence the absolute value of the amplitude behaves as $\sim e^{-2\pi\omega}$ also in this case.

The limit III is otherwise the same as the limit II except that $t+u = 8 - (\vec{k}^\perp)^2(1 + \cos \theta)$ is fixed. The asymptotics is given by

$$\begin{aligned} A_2 &\simeq \frac{i\pi e^{i\frac{\pi s}{2}}(2\pi\lambda)^{2i\omega}}{2 \sinh 2\pi\omega} \frac{\pi}{\Gamma\left(\frac{s+u}{2}\right) \sin \frac{\pi s}{2}} \left(-\frac{s}{2}\right)^{\frac{s+u}{2}-1}; \quad \frac{1 + \cos \theta}{2} > \frac{(\vec{k}^\parallel)^2}{(\vec{k}^\perp)^2} \\ A_2 &\simeq \frac{i\pi e^{i\frac{\pi s}{2}}(2\pi\lambda)^{2i\omega}}{2 \sinh 2\pi\omega} \frac{\pi e^{i\frac{\pi u}{2}}}{\Gamma\left(\frac{t+u}{2} - 2\right) \sin \frac{\pi t}{2}} \left(-\frac{t}{2}\right)^{\frac{t+u}{2}-3}; \quad \frac{1 + \cos \theta}{2} < \frac{(\vec{k}^\parallel)^2}{(\vec{k}^\perp)^2}. \end{aligned} \quad (49)$$

That is, in the former case we reproduce (48). Again, the absolute value of the amplitude vanishes as $\sim e^{-2\pi\omega}$.

Let us finally consider string production in an arbitrary direction. We take $\omega \rightarrow \infty$ with the parametrization

$$\begin{aligned}(\vec{k}^{\parallel})^2 &= \vec{k}^2 \cos^2 \psi = (4 + \omega^2) \cos^2 \psi \\ (\vec{k}^{\perp})^2 &= \vec{k}^2 \sin^2 \psi = (4 + \omega^2) \sin^2 \psi ,\end{aligned}\tag{50}$$

where $0 < \psi < \pi/2$ (such that the above cases I-III correspond to the endpoints, see Figure 2). We find the leading one of the following asymptotics:

$$\begin{aligned}A_2 &\sim (2\pi\lambda)^{2i\omega} e^{-2\pi\omega} e^{-i\pi\omega^2 \cos^2 \psi} \left[\left(\frac{1 + \cos \theta}{2} \right)^{\frac{1 + \cos \theta}{2}} \left(\frac{1 - \cos \theta}{2} \right)^{\frac{1 - \cos \theta}{2}} \right]^{\omega^2 \sin^2 \psi} \\ A_2 &\sim (2\pi\lambda)^{2i\omega} e^{-2\pi\omega} e^{-i\pi\omega^2 \left(\cos^2 \psi + \frac{1 - \cos \theta}{2} \sin^2 \psi \right)} \left[\left(\frac{\frac{1 - \cos \theta}{2} \sin^2 \psi}{\cos^2 \psi + \frac{1 - \cos \theta}{2} \sin^2 \psi} \right)^{\frac{1 - \cos \theta}{2} \sin^2 \psi} \right. \\ &\quad \left. \times \left(\frac{\cos^2 \psi}{\cos^2 \psi + \frac{1 - \cos \theta}{2} \sin^2 \psi} \right)^{\cos^2 \psi} \right]^{\omega^2} .\end{aligned}\tag{51}$$

The amplitudes vanish very fast $\sim \exp(-C\omega^2)$ due to the terms with the square brackets. It is easy to check that the coefficient C is positive.

A Correlators and kinematics

In this appendix we write the bulk two-point amplitude in terms of the Mandelstam variables often used in the literature. Let us start by giving a heuristic argument to motivate the definition of the variables. For the moment let us ignore the energy transfer from the D-brane to the strings which is possible due to the half S-brane deformation. Consider the $2 \rightarrow 2$ scattering *tachyon* (k_1) + *D-brane* (p_1) $\rightarrow$ *tachyon* (k_2) + *D-brane* (p_2), with the associated momenta in brackets. Breaking into parallel

and perpendicular components,

$$\begin{aligned}
k_1 &= (k_1^{\parallel}, \vec{k}_1^{\perp}) \\
p_1 &= (0, -\vec{k}_1^{\perp}) \\
k_2 &= (k_2^{\parallel}, \vec{k}_2^{\perp}) \\
p_2 &= (0, -\vec{k}_2^{\perp}) .
\end{aligned} \tag{52}$$

On-shell conditions and momentum conservation in parallel directions give

$$\begin{aligned}
k_1^2 &= k_2^2 = 4 \\
k_1^{\parallel} &= k_2^{\parallel} \\
|\vec{k}_1^{\perp}| &= |\vec{k}_2^{\perp}| .
\end{aligned} \tag{53}$$

So we obtain the Mandelstam variables

$$\begin{aligned}
\tilde{s} &= (k_1 + p_1)^2 = (k_2 + p_2)^2 = (k_1^{\parallel})^2 = (k_2^{\parallel})^2 = \frac{1}{2}s \\
\tilde{t} &= (k_1 - k_2)^2 = (p_1 - p_2)^2 = (\vec{k}_1^{\perp} - \vec{k}_2^{\perp})^2 = k_1^2 + k_2^2 - 2k_1 \cdot k_2 = 8 + 2t \\
\tilde{u} &= (k_1 - p_2)^2 = (k_2 - p_1)^2 = (k_1^{\parallel})^2 + (\vec{k}_1^{\perp} + \vec{k}_2^{\perp})^2 = 16 - \tilde{t} - 3\tilde{s} ,
\end{aligned} \tag{54}$$

where the variables without tildes match with the conventions of [14].¹¹ The last line of (54) is consistent with the relation

$$\tilde{s} + \tilde{t} + \tilde{u} = \text{sum of squared masses} = 8 + (\vec{k}_1^{\perp})^2 + (\vec{k}_2^{\perp})^2 = 16 - 2\tilde{s} . \tag{55}$$

Consider then the bulk two-point tachyon amplitude

$$\begin{aligned}
A_2 &= \int dx^0 d\vec{x}_{\parallel} e^{i(k_1+k_2) \cdot x_{\parallel}} \left\{ \int \prod_{a=1}^2 \frac{d^2 w_a}{2\pi} \left\langle \prod_{a=1}^2 e^{ik_a \cdot X'(w_a, \bar{w}_a)} \right\rangle \right. \\
&\quad \left. + \sum_{N=1}^{\infty} \frac{(-z)^N}{N!} \int \prod_{i=1}^N \frac{dt_i}{2\pi} \prod_{a=1}^2 \frac{d^2 w_a}{2\pi} \left\langle \prod_{i=1}^N e^{X'^0(t_i)} \prod_{a=1}^2 e^{ik_a \cdot X'(w_a, \bar{w}_a)} \right\rangle \right\} .
\end{aligned} \tag{56}$$

The singular self-contractions will be dropped. The first term in the series would give the amplitude for scattering from a stable D-brane. It contains the correlator

$$K_1 = \left\langle \prod_{a=1}^2 e^{ik_a \cdot X'(w_a, \bar{w}_a)} \right\rangle . \tag{57}$$

Working out the contractions gives

$$\begin{aligned}
K_1 &= \exp \left\{ \frac{1}{2} \sum_{a,b} \{ k_a^{\parallel} \cdot k_b^{\parallel} [\ln |w_a - w_b| + \ln |1 - w_a \bar{w}_b|] \right. \\
&\quad \left. + \vec{k}_a^{\perp} \cdot \vec{k}_b^{\perp} [\ln |w_a - w_b| - \ln |1 - w_a \bar{w}_b|] \} \right\} .
\end{aligned}$$

¹¹Notice that k_2 has opposite sign in [14].

For the next term in (56) we need to evaluate the correlator

$$K_2 = \left\langle \prod_{i=1}^N e^{X'^0(t_i)} \prod_{a=1}^2 e^{ik_a \cdot X'(w_a, \bar{w}_a)} \right\rangle . \quad (58)$$

We find

$$K_2 = \prod_{i < j} |e^{it_i} - e^{it_j}|^2 \prod_{ia} |1 - w_a e^{-it_i}|^{2\xi_a} \cdot K_1 , \quad (59)$$

where $\xi_a = -i\omega_a$. Let us naively generalize the above definitions of the Mandelstam variables to the case where the energy transfer is not zero by

$$\begin{aligned} k_1 \cdot k_2 &= s \\ (k_1^\parallel)^2 - (\vec{k}_1^\perp)^2 &= t - 4 , \end{aligned} \quad (60)$$

where we crossed $s \leftrightarrow t$ to obtain a setting that corresponds to the production of two strings. Then, setting $w_1 = r, w_2 = 0$, we get for the amplitude

$$A_2 = \delta(\vec{k}_1^\parallel + \vec{k}_2^\parallel) \int dx^0 e^{(\xi + \xi_2)x^0} \sum_{N=0}^{\infty} (-z)^N T(N) , \quad (61)$$

where

$$T(N=0) = T(N=1) = \int dr r K_1(r) = \int dr r r^s (1-r^2)^{(t/2)-2} \quad (62)$$

and for $N \geq 2$,

$$T(N) = \int dr r r^s (1-r^2)^{(t/2)-2} \left(\frac{1}{N!} \right) \int \prod_{i=1}^N \frac{dt_i}{2\pi} \prod_{i < j} |e^{it_i} - e^{it_j}|^2 \prod_i |1 - r e^{-it_i}|^{2\xi} . \quad (63)$$

B Schur polynomial method

Let us first discuss some properties of the Schur polynomials. They are symmetric polynomials of N variables $x_1, \dots, x_N$, denoted by $s_\lambda(x_1, x_2, \dots, x_N)$ where $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_N)$ is a partition of $|\lambda| = \lambda_1 + \lambda_2 + \dots + \lambda_N$ with $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_N \geq 0$. The partition may be identified with a Young diagram where the i th row has λ_i boxes. The polynomials may be defined by

$$s_\lambda(x_i) = \frac{\det \left[x_i^{\lambda_j + N - j} \right]_{i,j=1,\dots,N}}{\det \left[x_i^{N-j} \right]_{i,j=1,\dots,N}} , \quad (64)$$

where the denominator is the Vandermonde determinant $\Delta(x_1, x_2, \dots, x_N)$. The definition may be extended to partitions having more than N nonzero elements λ_i (or

to Young diagrams having more than N rows) by setting these polynomials to zero. We denote by $\ell(\lambda)$ the index of the last nonzero element (or the height of the corresponding Young diagram).

The polynomials have the following well known identities [47]

$$\prod_{i=1}^{N_x} \prod_{j=1}^{N_y} (1 + x_i y_j) = \sum_{\lambda} s_{\lambda}(x_i) s_{\lambda'}(y_i) \quad (65)$$

$$\prod_{i=1}^{N_x} \prod_{j=1}^{N_y} \frac{1}{1 - x_i y_j} = \sum_{\lambda} s_{\lambda}(x_i) s_{\lambda}(y_i) , \quad (66)$$

where λ' is the conjugate partition of λ , *i.e.*, λ'_i are the number of boxes in the columns of the Young diagram of λ . Notice that since $s_{\lambda}(x_i)$ vanishes if $\ell(\lambda) > N_x$, the sum over λ is restricted to a finite set of partitions with $\ell(\lambda) \leq N_x$ and $\lambda_1 \leq N_y$ in the first identity, as expected since the left hand side is a polynomial in x_i and y_j . One can also write down a generalized binomial theorem

$$\prod_{i=1}^N (1 - x_i)^{\xi} = \sum_{\lambda} c_{\lambda}(\xi) s_{\lambda}(x_i) , \quad (67)$$

where the coefficients $c_{\lambda}(\xi)$ are independent of N and polynomials in ξ . They are well known and are related to (65). When ξ is a positive integer we can set in (65) $N_y = \xi$ and $y_1 = -1 = y_2 = \dots = y_{\xi}$ whence we see that the coefficient $c_{\lambda}(\xi)$ equals $s_{\lambda'}(y_i = -1)$. The result may be expressed in various forms:

$$\begin{aligned} c_{\lambda}(\xi) &= (-1)^{|\lambda|} s_{\lambda'}(y_i = 1) = (-1)^{|\lambda|} \prod_{1 \leq i < j \leq \xi} \frac{\lambda'_i - i - \lambda'_j + j}{j - i} \\ &= (-1)^{|\lambda|} \frac{\Delta(\lambda'_{\xi} + 1, \lambda'_{\xi-1} + 2, \dots, \lambda'_1 + \xi)}{(\xi - 1)! \dots 1!} \\ &= (-1)^{|\lambda|} \prod_{m \in \lambda} \frac{1}{h_m} (\xi + i(m) - j(m)) , \end{aligned} \quad (68)$$

where the last form gives the number of terms in the Schur polynomial in terms of the “hook length” h_m (it also equals the number of the semistandard Young tableaux of the form λ' and the dimension of the representation of $SU(\xi)$ characterized by λ'). Here $i(m)$ ($j(m)$) is the number of row (column) of the box m in λ . Since c_{λ} are indeed known to be polynomials in ξ , the result in the last form readily extends to all complex values of ξ . We may thus write the generalized binomial theorem as

$$\prod_{i=1}^N (1 - r x_i)^{\xi} = \sum_{\lambda} (-r)^{|\lambda|} \prod_{m \in \lambda} \frac{1}{h_m} (\xi + i(m) - j(m)) s_{\lambda}(x_i) , \quad (69)$$

where we rescaled all variables by r .

Let us then concentrate on the two-point function Z_2 of (8). By using the formulae (69) we may write the “cross-term” in the integrand as

$$\prod_{i=1}^N |1 - re^{-it_i}|^{2\xi} = \prod_{i=1}^N (1 - re^{it_i})^\xi (1 - re^{-it_i})^\xi = \sum_{\lambda, \bar{\lambda}} (-r)^{|\lambda|+|\bar{\lambda}|} c_\lambda(\xi) c_{\bar{\lambda}}(\xi) s_\lambda(x_i) s_{\bar{\lambda}}(x_i^*) , \quad (70)$$

where $x_i = e^{it_i}$. As the Schur polynomials are orthogonal with respect to the weight function of Z_2 we immediately get

$$Z_2(r, \xi; N) = \sum_{\lambda, \ell(\lambda) \leq N} r^{2|\lambda|} |c_\lambda(\xi)|^2 = \sum_{\lambda, \ell(\lambda) \leq N} r^{2|\lambda|} \prod_{m \in \lambda} \frac{1}{h_m^2} (\xi + i(m) - j(m))^2 , \quad (71)$$

where the constraint $\ell(\lambda) \leq N$ appears since the polynomials $s_\lambda(x_i)$ vanish for $\ell(\lambda) > N$. If ξ is a positive integer the sum over λ is finite because the coefficients $c_\lambda(\xi)$ vanish for $\lambda_1 > \xi$. Moreover, if ξ is a negative integer and $N \geq |\xi|$ the sum can be done explicitly as a special case of the general result found in [24]:

$$Z_2(r, \xi; N) = (1 - r^2)^{-\xi^2} ; \quad \xi = -1, -2, \dots, -N . \quad (72)$$

C Solutions to the potential problems

We are interested in solving potential problems in classical electrostatics where the conductors are pieces of the arc of the unit circle. The general potential problem has as conductors $\hat{n}$ separate arcs of the unit circle. We find it useful to map the disk onto the upper half plane by the conformal map

$$w \mapsto z = i\beta \frac{1-w}{1+w} \equiv q(w) \quad (73)$$

with the understanding that we work in the compactified complex plane with the ∞ -point included. Here β is a real parameter.

The analytic properties of the complex electric field allow us to write down the solution in a special form [47]. Let us assume for a moment that we have two conductors, $\hat{n} = 2$, which lie at $[a, b]$ and at $[c, d]$. We can then define the following functions

$$\begin{aligned} g(z) &= \sqrt{z-a} \sqrt{z-b} \sqrt{z-c} \sqrt{z-d} \\ h(z) &= \sqrt{z-a} \sqrt{b-z} \sqrt{c-z} \sqrt{d-z} , \end{aligned} \quad (74)$$

where the principal branch of the square root function is used. Then $g(z)$ is analytic everywhere except on the conductors where it has branch cuts, whereas $h(z)$ is analytic over the conductors, but has branch cuts in the gap regions.

Generalization to $\hat{n}$ conductors is found by adding more terms to $g(z)$ and $h(z)$. We choose the branches such that

$$h(z) = \mp ig(z) , \quad (75)$$

where the minus sign holds in the upper half plane and the plus sign holds in the lower half plane. It is then possible to show that, when exposed to an appropriate external (conjugate) electric field $E_{\text{ext}}(z)$, a solution for the (conjugate) electric field due to the conductors reads

$$E_c(z) = \frac{1}{\pi} g(z) \int_{\text{cond}} dt \frac{\text{Re } E_{\text{ext}}(t)}{(z-t)h(t)} , \quad (76)$$

where the integration is over the conductors. Notice that the solution is bounded at the conductor endpoints. It is well defined everywhere except on the conductors, where it has discontinuities. The charge density¹² is proportional to the discontinuity and becomes

$$\rho(z) = \frac{1}{\pi^2} h(z) \int_{\text{cond}} dt \frac{1}{h(t)} \frac{\text{Re } E_{\text{ext}}(z) - \text{Re } E_{\text{ext}}(t)}{z-t} . \quad (77)$$

The $2\hat{n}$ endpoints of the conductors are not arbitrary parameters but are subject to constraints. In particular, these parameters (the constants a , b , c , and d in the $\hat{n} = 2$ case) are partially fixed by the asymptotics of the electric field

$$E_c(z) \sim \frac{N}{z} \quad (78)$$

for $z \rightarrow \infty$ where N is the total electric charge on the conductors. This gives

$$\begin{aligned} 0 &= \int_{\text{cond}} dt \frac{t^k \text{Re } E_{\text{ext}}(t)}{h(t)} , & k = 0, \dots, \hat{n} - 1 \\ \pi N &= \int_{\text{cond}} dt \frac{t^{\hat{n}} \text{Re } E_{\text{ext}}(t)}{h(t)} . \end{aligned} \quad (79)$$

There are $\hat{n} - 1$ parameters left free, which are identified as the potential differences between the conducting planes. We will set these to zero and thus require

$$\text{Re} \int_{\mathcal{C}_k} dz E(z) = 0 , \quad k = 2, \dots, \hat{n} , \quad (80)$$

where

$$E(z) = E_c(z) + E_{\text{ext}}(z) \quad (81)$$

is the total electric field and the curve $\mathcal{C}_k$ connects the first conductor with the k th one without intersecting the other conductors, for example.

¹²For brevity, we omit the subscript 0 which was used in the main text.

For the case of interest to us, the external field is due to n point like charges,

$$E_{\text{ext}}(z) = \sum_{a=1}^n \xi_a \frac{1}{z - z_a} . \quad (82)$$

For this configuration the integrals above can be calculated exactly by using contour integration methods. We find

$$\begin{aligned} E_c(z) &= \frac{g(z)}{2} \sum_a \xi_a \left[\frac{1}{g(z_a)(z - z_a)} + \frac{1}{g(z_a^*)(z - z_a^*)} \right] - \sum_a \xi_a \frac{z - x_a}{(z - z_a)(z - z_a^*)} \\ E(z) &= \frac{g(z)}{2} \sum_a \xi_a \left[\frac{1}{g(z_a)(z - z_a)} + \frac{1}{g(z_a^*)(z - z_a^*)} \right] + \sum_a \xi_a \frac{iy_a}{(z - z_a)(z - z_a^*)} \\ \rho(z) &= -\frac{h(z)}{2\pi} \sum_a \xi_a \left[\frac{1}{g(z_a)(z - z_a)} + \frac{1}{g(z_a^*)(z - z_a^*)} \right] , \end{aligned} \quad (83)$$

where $z_a = x_a + iy_a$. The asymptotic conditions imply

$$\begin{aligned} 0 &= \sum_a \xi_a \left[\frac{z_a^k}{g(z_a)} + \frac{(z_a^*)^k}{g(z_a^*)} \right] , \quad k = 0, \dots, \hat{n} - 1 \\ N + \sum_a \xi_a &= \frac{1}{2} \sum_a \xi_a \left[\frac{z_a^{\hat{n}}}{g(z_a)} + \frac{(z_a^*)^{\hat{n}}}{g(z_a^*)} \right] . \end{aligned} \quad (84)$$

The potential and the total energy of the system are of special interest to us. We can integrate the complex electric field in (83) to give

$$\begin{aligned} V_c(z) &= V(z) + \sum_a \xi_a \log(z - z_a) \\ V(z) &= \frac{1}{2} \sum_a \xi_a [-\log(z - z_a) + \log(z - z_a^*)] \\ &\quad + \lim_{R \rightarrow \infty} \left\{ \frac{1}{2} \int_z^R dt g(t) \sum_a \xi_a \left[\frac{1}{g(z_a)(t - z_a)} + \frac{1}{g(z_a^*)(t - z_a^*)} \right] \right. \\ &\quad \left. - \left(N + \sum_a \xi_a \right) \log R \right\} . \end{aligned} \quad (85)$$

Notice that this solution has the asymptotics required by our definition (16) (or more precisely by its natural generalization to the half plane)

$$V(z) = - \left(N + \sum_a \xi_a \right) \log z + \mathcal{O} \left(\frac{1}{z} \right) , \quad (86)$$

so that the constant term of the expansion in $1/z$ is zero.

Let us then write down explicitly the solutions for the disk, *i.e.*, apply the transformation $q(w)$ of (73) (with, say $\beta = 1$). To do so, we should start with the configuration

where charges $\xi_1, \dots, \xi_n$ are located at arbitrary points $z_1 = q(w_1), \dots, z_n = q(w_n)$, and an additional charge $\xi_{n+1} = -N - \sum_a \xi_a$ is located at $z = q(\infty)$. Let us denote the corresponding electric field and potential, as given by eqs. (83) and (85), by $\tilde{E}$ and $\tilde{V}$, respectively.

The electric field on the disk may be then written as

$$\begin{aligned} E(w) &= \tilde{E}(q(w)) \\ E_c(w) &= \tilde{E}_c(q(w)) - \frac{N}{q(w) - q(\infty)} \end{aligned} \quad (87)$$

and integration gives the potential on the disk

$$\begin{aligned} V(w) &= \tilde{V}(q(w)) - \lim_{R \rightarrow \infty} \left[\int_{q(R)}^{\infty} dz \tilde{E}(z) + \left(N + \sum_a \xi_a \right) \log R \right] \\ V_c(w) &= \tilde{V}_c(q(w)) + N \log [q(w) - q(\infty)] \\ &\quad - \lim_{R \rightarrow \infty} \left[\int_{q(\infty)}^R dz \tilde{E}(z) - N \log R \right] - N \log \frac{d}{dt} q(1/t) \Big|_{t=0} . \end{aligned} \quad (88)$$

Here the integrals are independent of w . They were added to achieve the correct asymptotics,

$$V(w) = - \left(N + \sum_a \xi_a \right) \log w + \mathcal{O} \left(\frac{1}{w} \right) ; \quad V_c(w) = -N \log w + \mathcal{O} \left(\frac{1}{w} \right) . \quad (89)$$

Finally, the potential on the conductors is found as

$$U_0 = \text{Re } V(w_0) , \quad (90)$$

where w_0 is any point on the conductors, and the “interaction” energy is given by

$$\mathcal{E}_{c-\xi} = \sum_a \xi_a \text{Re } V_c(w_a) . \quad (91)$$

The total energy then reads (see (19) above)

$$\mathcal{E}_{\text{tot}} = \frac{N}{2} U_0 + \frac{1}{2} \mathcal{E}_{c-\xi} + \mathcal{E}_{\xi} , \quad (92)$$

where

$$\mathcal{E}_{\xi} = - \sum_{a < b} \xi_a \xi_b \log(w_a - w_b) \quad (93)$$

is the energy linked to the self-interactions of the external charges. This trivial term was not discussed in the main text since its contribution was embedded in the explicit w_1, w_2 dependence of (6) that was treated separately.
